Abstract

Introduction: Xeroderma pigmentosum (XP) is a very rare skin disorder where a person is highly sensitive to sunlight, has premature skin aging and is prone to developing skin cancers. This is caused by a cellular hypersensitivity to ultraviolet (UV) light as a result of a defect in the DNA repair system, and is reported to be associated with ocular surface disorders such as conjunctival malignancy and pterygium. In this study, I report a case of successful Amniotic Membrane Graft (AMG) in a XP patient after surgical resection of pterygium.

Case: 15 years old girl, who is suffering from XP, presented to our clinic for treatment of her bilateral pterygium. Surgical resection was performed for a nasal, rapidly progressive pterygium in her left eye associated with multi-layer amniotic membrane grafting.

Examination: Re-epithelialization over the AMG was completed after 14 days. Best corrected visual acuity was improved after two months post operatively. No recurrence was noticed during one year of regular follow up.

Conclusions: AMG as an adjuvant to primary pterygium resection is effective in patient with XP. Further more, multi-layer AMG is beneficial in protecting bare sclera and medial rectus muscle from mechanical injury after pterygium resection.

Introduction

Xeroderma pigmentosum (XP) is a rare, autosomal recessive, precancerous skin disorder; and is characterized by cellular hypersensitivity to ultraviolet light as a result of defect in DNA repair system [1]. XP is proved to be linked to ocular surface disorders such as conjunctival tumors and pterygium [2]. Amniotic Membrane Graft (AMG) is validated to be useful in reconstructing many ocular surface disorders, including pterygium [3-5]. In our study, we report a case of successful surgical treatment of pterygium with multi-layer AMG in a XP patient.

Case Report

15 years old girl diagnosed with XP was presented to our clinic for treatment of her bilateral pterygium. Family history of XP was negative. Surgery was performed under general anesthesia for a rapidly progressive pterygium that was encroaching over the cornea of the left eye. The pterygium and underlying fibrous tissue were excised thoroughly, and abnormal scar tissue on the corneal surface was polished. Minimal cauterisation was used to control the bleeding. The size of the bare scleral bed (in mm) was measured in the position that the eye deviated away from the side of the lesion in order to prevent mechanical injury after pterygium resection.
The patient was followed up monthly for the first 6 months and at 3-month intervals. Re-epithelialization over the AMG was completed after 14 days. Corrected visual acuity improved after two months post operatively. During the first year regular follow-up, neither recurrence nor any post operative complication, such as graft rejection, symblepharon, or chronic inflammation, was observed.

The primary goal in pterygium surgery is to remove the fibrovascular growth that will eventually result in permanent fibrosis in the pupillary axis and to reduce recurrence. Moreover, the surgeon should aim to reduce resection-related complications, increase patient comfort in the post-operative period, and accomplish a justifiable appearance. Although, the diverse modes used in the management of pterygium have concentrated principally on minimizing the recurrence rate.

AMG has recently been used as a complement to pterygium surgery for arresting recurrence and for covering large conjunctival defects [3]. Ma., et al. [5] recently reported that AMG alone attains a lower recurrence rate of 3.8%, as compared to 5.4% for conjunctival auto graft in primary pterygium surgery. Moreover the recurrence rate of pterygium in an XP patient has not been reported yet, the pterygium in this case was considered as highly assertive regarding the youth of the patient and that 40% of XP patients are reported to have bilateral pterygia [2]. Based on the data of Maetal [5] and the fact that the pterygium in this patient was large, we performed AMG.

Post-Operative Follow-Up

After surgery, biomicroscopic examination was performed on the first day, and topical antibiotic (ofloxacin 0.3%; Allergan Pharmaceuticals, Dublin, Ireland) and steroid (dexamethasone 0.1%; Alcon, Fort Worth, TX, USA) drops were given four times daily. Patient was examined weekly and the medications were tapered and discontinued until the end of the first month. Patient was required to wear a protective eye shield for 14 days after surgery.

The patient was followed up monthly for the first 6 months and at 3-month intervals. Re-epithelialization over the AMG was completed after 14 days. Corrected visual acuity improved after two months post operatively. During the first year regular follow-up, neither recurrence nor any post operative complication, such as graft rejection, symblepharon, or chronic inflammation, was observed.

Discussion

The primary goal in pterygium surgery is to remove the fibrovascular growth that will eventually result in permanent fibrosis in the pupillary axis and to reduce recurrence. Moreover, the surgeon should aim to reduce resection-related complications, increase patient comfort in the post-operative period, and accomplish a justifiable appearance. Although, the diverse modes used in the management of pterygium have concentrated principally on minimizing the recurrence rate.

AMG has recently been used as a complement to pterygium surgery for arresting recurrence and for covering large conjunctival defects [3]. Ma., et al. [5] recently reported that AMG alone attains a lower recurrence rate of 3.8%, as compared to 5.4% for conjunctival auto graft in primary pterygium surgery. Moreover the recurrence rate of pterygium in an XP patient has not been reported yet, the pterygium in this case was considered as highly assertive regarding the youth of the patient and that 40% of XP patients are reported to have bilateral pterygia [2]. Based on the data of Maetal [5] and the fact that the pterygium in this patient was large, we performed AMG.

Conclusion
The present case advocate that multilayer AMG is efficient for pterygium, even in a young XP patient where pterygium is supposedly highly active and easy to recur. Also, the multi-layer AMG appears to be beneficial compared to the single-layer method to nullify melting caused by severe inflammation and to shelter bare sclera and muscle especially when the patient's compliance is not enough. The use of fibrin glue was safe and effective with no major complications. Further comparative study between single and multi-layer AMG is recommended to certify the clinical value of this modality of AMG.
